1 Introduction

Given the opportunity to review the design document and related smart contract source code of the `slisBNBOracle` contract, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

1.1 About slisBNBOracle

This audit covers the specific oracle contract, i.e., `slisBNBOracle`. The oracle is used in a set of smart contracts that enable users to earn rewards for providing liquidity to the `MakerDAO` protocol. This specific oracle derives the price by combining the `BNB/USD` price oracle and the exchange rate of `Stake Manager` of `BNB`. The basic information of the audited contract is as follows:

Table 1.1: Basic Information of Audited Contracts

Item	Description
Target	slisBNBOracle Contract
Type	EVM Smart Contract
Language	Solidity
Audit Method	Whitebox
Latest Audit Report	April 18, 2024

In the following, we show the Git repository of reviewed files and the commit hash values used in this audit. Note this repository has a number of smart contracts and directories and our audit only covers the following contract: `contracts/oracle/SlisBnbOracle.sol`.

- https://github.com/lista-dao-contracts.git (ea43e74)

And this is the commit ID after all fixes for the issues found in the audit have been checked in:

- https://github.com/lista-dao-contracts.git (TBD)

1.2 About PeckShield

PeckShield Inc. [5] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

Table 1.2: Vulnerability Severity Classification

Impact \ Likelihood	*High*	*Medium*	*Low*
High	Critical	High	Medium
Medium	High	Medium	Low
Low	Medium	Low	Low

1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [4]:

- Likelihood represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the

Table 1.3: The Full List of Check Items

Category	Check Item
Basic Coding Bugs	Constructor Mismatch
	Ownership Takeover
	Redundant Fallback Function
	Overflows & Underflows
	Reentrancy

Additional Recommendations	Avoiding Use of Variadic Byte Array
	Using Fixed Compiler Version
	Making Visibility Level Explicit
	Making Type Inference Explicit
	Adhering To Function Declaration Strictly
	Following Other Best Practices

contract is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.

- Semantic Consistency Checks: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.

- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [3], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
Configuration	Weaknesses in this category are typically introduced during the configuration of the software.
Data Processing Issues	Weaknesses in this category are typically found in functionality that processes data.
Numeric Errors	Weaknesses in this category are related to improper calculation or conversion of numbers.
Security Features	Weaknesses in this category are concerned with topics like authentication, access control, confidentiality, cryptography, and privilege management. (Software security is not security software.)
Time and State	Weaknesses in this category are related to the improper management of time and state in an environment that supports simultaneous or near-simultaneous computation by multiple systems, processes, or threads.
Error Conditions, Return Values, Status Codes	Weaknesses in this category include weaknesses that occur if a function does not generate the correct return/status code, or if the application does not handle all possible return/status codes that could be generated by a function.
Resource Management	Weaknesses in this category are related to improper management of system resources.
Behavioral Issues	Weaknesses in this category are related to unexpected behaviors from code that an application uses.
Business Logics	Weaknesses in this category identify some of the underlying problems that commonly allow attackers to manipulate the business logic of an application. Errors in business logic can be devastating to an entire application.
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used for initialization and breakdown.
Arguments and Parameters	Weaknesses in this category are related to improper use of arguments or parameters within function calls.
Expression Issues	Weaknesses in this category are related to incorrectly written expressions within code.
Coding Practices	Weaknesses in this category are related to coding practices that are deemed unsafe and increase the chances that an exploitable vulnerability will be present in the application. They may not directly introduce a vulnerability, but indicate the product has not been carefully developed or maintained.

2 Findings

2.1 Summary

Here is a summary of our findings after analyzing the implementation of the `slisBNBOracle` contract. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logic, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings	
Critical	0	
High	0	
Medium	0	
Low	1	■
Informational	1	■
Total	2	

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities that need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 1 low-severity vulnerability and 1 informational recommendation.

Table 2.1: Key slisBNBOracle Contract Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Informational	Improved Constructor/Initialization Logic in SlisBnbOracle	Coding Practices	
PVE-002	Low	Improved Price Validation in SlisBnbOracle::peek()	Coding Practice	

Beside the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

3 | Detailed Results

3.1 Improved Constructor/Initialization Logic in SlisBnbOracle

- ID: PVE-001
- Severity: Informational
- Likelihood: N/A
- Impact: N/A
- Target: `SlisBnbOracle`
- Category: Coding Practices [2]
- CWE subcategory: CWE-1126 [1]

Description

To facilitate possible future upgrade, the specific `SlisBnbOracle` contract is instantiated as a proxy with its actual logic contract in the backend. While examining the related contract construction and initialization logic, we notice current construction can be improved.

In the following, we shows the initialization routine. We notice its constructor has no payload and can be improved by adding the following statement, i.e., `_disableInitializers();`. Note this statement is called in the logic contract where the initializer is locked. Therefore any user will not be able to call the `initialize()` function in the state of the logic contract and perform any malicious activity. Note that the proxy contract state will still be able to call its own initialize function since the constructor does not effect the state of the proxy contract.

```
contract SlisBnbOracle is Initializable {

  AggregatorV3Interface internal priceFeed;
  // @dev Stake Manager Address
  address internal constant stakeManagerAddr = 0x1adB950d8bB3dA4bE104211D5AB038628e477fE6;
  // @dev New price feed address
  address internal constant bnbPriceFeedAddr = 0xC5A35FC58EFDC4B88DDCA51AcACd2E8F593504bE;

  function initialize(address aggregatorAddress) external initializer {
    priceFeed = AggregatorV3Interface(aggregatorAddress);
  }
```

```
    ...
}
```

Listing 3.1: `SlisBnbOracle::initialize()`

Recommendation Improve the above-mentioned constructor routine in `SlisBnbOracle`.

Status

3.2 Improved Price Validation in SlisBnbOracle::peek()

- ID: PVE-002
- Severity: Low
- Likelihood: Low
- Impact: Low
- Target: `SlisBnbOracle`
- Category: Coding Practices [2]
- CWE subcategory: CWE-1126 [1]

Description

The `SlisBnbOracle` contract has a rather straightforward functionality in providing the requested latest price of staked `BNB`. While examining the current implementation, we notice it can be improved to validate the returned price is not zero.

In the following, we show the implementation of the related `peek()` routine. As the name indicates, it is used to query the latest price of the staked `BNB`. And the latest price is derived by firstly querying current `BNB` price from `bnbPriceFeedAddr` (located at `0xC5A35FC58EFDC4B88DDCA51AcACd2E8F593504bE`) and then multiplying the queried `BNB` price with the latest exchange rate from `BNB Stake Manager` (located at `0x1adB950d8bB3dA4bE104211D5AB038628e477fE6`). The returned `BNB` price can be further validated to ensure it is not equal to 0 (line 34).

```
23  function peek() public view returns (bytes32, bool) {
24    (
25    /*uint80 roundID*/,
26      int price,
27    /*uint startedAt*/,
28      uint timeStamp,
29    /*uint80 answeredInRound*/
30    ) = AggregatorV3Interface(bnbPriceFeedAddr).latestRoundData();
31
32    require(block.timestamp - timeStamp < 300, "BnbOracle/timestamp-too-old");
33
34    if (price < 0) {
35      return (0, false);
36    }
37    return (bytes32(uint(price) * ISnBnbStakeManager(stakeManagerAddr).convertSnBnbToBnb
        (10**10)), true);
```

```
}
```

Listing 3.2: SlisBnbOracle :: peek()

Recommendation Revise the above routine to ensure the returned price is not 0.

Status

4 Conclusion

In this audit, we have analyzed the design and implementation of the specific oracle contract, i.e., `slisBNBOracle`. The oracle is used in a set of smart contracts that enable users to earn rewards for providing liquidity to the `MakerDAO` protocol. This specific oracle derives the price by combining the `BNB/USD` price oracle and the exchange rate of `Stake Manager` of `BNB`. The current code base is well structured and neatly organized. Those identified issues are promptly confirmed and addressed.

Meanwhile, we need to emphasize that smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
